# Coordinated Work Schedules and the Gender Wage Gap 

German Cubas<br>University of Houston<br>Chinhui Juhn<br>University of Houston<br>Pedro Silos<br>Temple University

May 2018

## Intro

- Women have made remarkable gains in the labor market over the past five decades.
- The rate of convergence in female and male earnings has stalled since 2000.
- The rate of convergence has stalled especially for college educated figure2

## Intro

- Bertrand, Goldin, and Katz (2010) follow career progression of Chicago MBAs.
- Men and women begin their careers with similar earnings but women are $60 \log$ points behind a decade later.
- Gap arises from career interruptions and lower hours related to children.
- Recent work on child penalty reinforce these findings, e.g. Kleven et al. (2018)

## Intro

- Goldin (2014) cites flexible work schedules as key in the "last chapter" of gender convergence
- What is the right way to measure flexiblility?
- Demand for long hours disadvantages women (Goldin, 2014; Erosa et. al., 2017; Gicheva, 2013; Cha and Wheeden, 2014; Cortes and Pan, 2016)

## Our Paper

- Focus on the timing of work and how it conflicts with the demands of family time.
- We look at observed hours chosen by workers.
- Work schedules at the occupational-level.

## Our Story

- The demand for family time is higher for women relative to men.
- It restricts their hours choices.
- It conditions their occupational choice.
- There are occupations in which workers are more productive if they work at the same time (need to coordinate) but there are others for which that is not important (do not need to coordinate).

## What do we do? <br> Facts

- We use American Time Use Surveys (ATUS) to establish the following facts
- Among married women and men with children, women have more "missing hours" from work
- Women correspondingly do more household care
- Occupations differ in terms of how work hours are bunched during peak hours
- Bunching is compensated but less so if women

## What do we do? Theory

- A general equilibrium model of occupational choice where:
- Occupations differs in terms of the productivity of workers when they balance working time during the day.
- Heterogenous workers, occupation-specific tastes.
- Household care and market goods. Women derive more utility from household care.

## Outline of the Talk

- Facts
- Theory
- Quantitative Exercises (preliminary results)

## Data

- 2003-2014 American Time Use Surveys (ATUS) and CPS. One respondent per household is drawn from the Current Population Survey.
- We focus on two activities, work and work-related activities and caring for and helping household members
- We focus on adults who are 18 to 65 years old and are full time workers.
- There are 108,426 respondents and 67,134 are full-time

## Timing of Work Across Occupations

## Timing of Work in Selected Occupations

Physicians, therapists,nurses, dentis Secretaries and Administrative Assist

Nursing, Psychiatric, and Home Health

Computer Operators First-Line Supervisors of Retail, non retail Sale:

## Measuring Bunching: The 8to5ratio

- Divide the day in three time intervals: 12 a.m.-8 a.m. (A), 8 a.m.-5 p.m.(B) and, 5 p.m.-12 a.m. (C)
- Aij, Bij, and Cij refer to the sum of minutes worked by individual $i$ in occupation $j$.
- Then, at the occupation level we have that

$$
\begin{aligned}
A_{j}=\sum_{i=1}^{N_{j}} w_{i} A_{i j}, B_{j} & =\sum_{i=1}^{N_{j}} w_{i} B_{i j}, C_{j}=\sum_{i=1}^{N_{j}} w_{i} C_{i j} \\
\text { ratio8to5 } j_{j} & =\frac{B_{j}}{A_{j}+B_{j}+C_{j}}
\end{aligned}
$$

## 8to5ratio - More Educated Workers

$$

## Summary

- Our regression coefficients indicate that one standard deviation in ratio8to5 leads to approximately 10 percent extra earnings for full time workers.
- Our regression coefficients indicate that one standard deviation in ratio8to5 leads to approximately 5 percent extra earnings gap for married women with children
- This is about one-sixth of the gender gap in earnings for this population

## Interpretation

- Our regression coefficients however reflect decisions, endogenous to production technology of market goods, production technology of home goods, preferences over home and market goods.
- Objects that are interrelated and difficult to control for
- How much of the observed earnings gap is due to each these factors?

## Interpretation

- Our regression coefficients however reflect decisions, endogenous to production technology of market goods, production technology of home goods, preferences over home and market goods.
- Objects that are interrelated and difficult to control for
- How much of the observed earnings gap is due to each these factors?
We add structure and conduct counterfactual experiments

## Model-Environment

- Mass-one continuum of male and female individuals that live 1 period. There are $J$ occupations and choose one of them.
- They consume home care and market goods. Home care purchased through time only.

$$
u(c, h)=(h)^{\nu^{s}}(c)^{1-\nu^{s}}
$$

- Individual draws a taste parameter $\theta_{i, j, g}$ from $F_{g}\left(\theta_{j}\right)$.

$$
\Omega_{i}=\left\{\theta_{i, 1}, \ldots, \theta_{i, J}\right\}
$$

## Model-Environment

- Workers decide:
- the split of their time between home and market, $h^{i}$ and $l^{i}$.
- the division of their time between the "prime" ( $l_{1}^{i}$ and $l_{2}^{i}$ ) and "kids" time ( $h_{1}^{i}$ and $h_{2}^{i}$ ).
- The total number of hours during the period is set to one, that means $h_{j, 1}^{i}+l_{j, 1}^{i}+h_{j, 2}^{i}+l_{j, 2}^{i}=1$ and $h_{j, 2}^{i}+l_{j, 2}^{i}=0.5$.
- The timing of work affects productivity:
$l_{j}^{i}=l_{j, 1}^{i}+l_{j, 2}^{i}-\left(0.5-l_{j, 1}^{i}\right)^{\alpha_{j}} \quad$ with $\quad \alpha_{j}=>0 \quad$ for $\quad j=1, \ldots, J$
- The timing of home production affects the production of home goods:

$$
h^{i}=\left(\left(h_{1}^{i}\right)^{\rho}+\left(h_{2}^{i}\right)^{\rho}\right)^{\frac{1}{\rho}}
$$

## Model-Individual's Decision Problem

- The amount of effective labor supplied by worker of gender $s$ in occupation $j$ is $l_{j}^{s}$. The supply of a unit of effective labor is compensated at a rate $w_{j}$.
- The value of occupation $j$ for an individual of gender $s$ reads as follows

$$
\begin{array}{r}
V_{j}^{s}\left(\theta_{j}^{s}\right)=\theta_{j}\left\{\max _{c^{s}, l_{j, 1}^{s}, l_{j, 2}^{s}, h_{j, 1}^{s}, h_{j, 2}^{s}}\left\{u\left(c^{s}, h^{s}\right)\right\}\right\} \\
\text { s.to. } \\
c^{s}=l_{j}^{s} w_{j} \\
h_{j, 2}^{s}+l_{j, 2}^{s}=0.5 \\
l_{j}^{s}=l_{j, 1}^{s}+l_{j, 2}^{s}-\left(0.5-l_{j, 1}^{s}\right)^{\alpha_{j}} \quad \text { with } \quad \alpha_{j} \geq 0 \\
h_{j, 1}^{s}=\left(\left(h_{j, 1}^{s}\right)^{\rho}+\left(h_{j, 2}^{s}\right)^{\rho}\right)^{\frac{1}{\rho}}
\end{array}
$$

## Model-Production

- There are $J$ intermediate good producers (occupations) according to $X_{j}=N_{j}$. They solve

$$
\max _{N_{j}} p_{j} X_{j}-N_{j} w_{j}, \quad \text { s.to } \quad X_{j}=N_{j}
$$

## Model-Production

- There are $J$ intermediate good producers (occupations) according to $X_{j}=N_{j}$. They solve

$$
\max _{N_{j}} p_{j} X_{j}-N_{j} w_{j}, \quad \text { s.to } \quad X_{j}=N_{j}
$$

- Final Goods Technology:

$$
Y_{j}=\prod_{j=1}^{J}\left\{X_{j}^{\kappa_{j}}\right\}
$$

Producers solve

$$
\max _{X_{1}, \ldots, X_{J}} \prod_{j=1}^{J}\left\{X_{j}^{\kappa_{j}}\right\}-\sum_{j=1}^{J} p_{j} X_{j}
$$

## Model-Production

- There are $J$ intermediate good producers (occupations) according to $X_{j}=N_{j}$. They solve

$$
\max _{N_{j}} p_{j} X_{j}-N_{j} w_{j}, \quad \text { s.to } \quad X_{j}=N_{j}
$$

- Final Goods Technology:

$$
Y_{j}=\prod_{j=1}^{J}\left\{X_{j}^{\kappa_{j}}\right\}
$$

Producers solve

$$
\max _{X_{1}, \ldots, X_{J}} \prod_{j=1}^{J}\left\{X_{j}^{\kappa_{j}}\right\}-\sum_{j=1}^{J} p_{j} X_{j}
$$

- In equilibrium $X_{j}=N_{j}$ and $p_{j}=w_{j}$.

## Taking the Model to the Data (I)

- Taste shocks distributed Frechet with common dispersion parameter.

$$
\operatorname{Prob}\left(\theta \leq \theta_{0}\right)=-\exp \left(-T_{j, g} \theta_{0}\right)^{-\xi}
$$

- Normalize $T_{j}=1$ for all $j$ for males.
- Parameters : $\left(\{\alpha\}_{j=1}^{22},\{\kappa\}_{j=1}^{22},\left\{T_{i, f}\right\}_{j=1}^{22}, \rho, \nu^{f}, \nu^{m}\right)$

## Taking the Model to the Data (II)

- The labor shares - $\kappa_{j}$ - equal ratio of earnings in each occupation as a share of total earnings.
- Choose the remaining parameters to match:
- Work bunching ratios by occupation.
- Share of females by occupation.
- Average hours of males and females.
- Ratio of work bunching ratio to household care bunching ratio.

## Coordination and the Gender Gap

- Correlation bunching ratio earnings per hour: 0.3
- Correlation bunching ratio gender gap: 0.96
- Gender Gap $4.4 \%$ ( $87 \%$ of data; $15 \%$ of overall).

## Three Experiments

- Equal coord. frictions - lowest- across occupations (maximum of $\alpha$ 's).
- Gender gap drops by $60 \%$
- Equal $\nu$ across females and males.
- Gender gap vanishes.
- Equal $T$ across occupations and gender.
- Gender gap rises by $7 \%$

## Final Remarks

- Using time diaries, we document that even full-time working women "miss" work and do more household care.
- We propose an alternative measure of "(in)flexibility" that characterizes occupations.
- We find a robust relationship between this measure and gender wage gap among married with children.
- Calibration of model suggests about 15 percent of gender wage gap is due to women's higher demand for home time

## Final Remarks

- Cook et al. (2018) find 5 to 7 percent gender wage gap in work with complete flexibility (Uber drivers)
- Experience, driving speed, and choice of when and where to drive explains the differences.
- Duchini et al (2018) study the effects of French school hours reform.
- When schools open on Wednesdays, women work more on Wednesdays, educated women and managers have biggest response

## Shift Work
